

Hosting Recommendation - one.com

Generated for Project Sentinel pre-coding readiness package.

Hosting Recommendation - one.com

Recommendation

For Project Sentinel, use a VPS, not shared web hosting.

The project is not only a static website. It is intended to become a Python-based cyber security operating environment with background services, APIs, event processing, storage, plugins, and potentially long-running workers. Shared web hosting is useful for websites, WordPress, email, PHP/MariaDB, and simple public pages, but it is not the right primary runtime for a custom security platform.

Best starting choice

Recommended starting option: ****one.com Managed VPS, Managed Cloud Server M****.

Reason:

- It provides 4 vCPU, 8 GB RAM, 200 GB NVMe SSD, 1 Gbit/s bandwidth, and unlimited data traffic according to the current one.com managed VPS page.
- Managed VPS includes support, automatic security updates, software patches, proactive monitoring, and backups.
- It runs Ubuntu and includes a managed software stack.

If budget is tight or you want to learn server administration yourself, use an unmanaged Ubuntu VPS instead. If you choose unmanaged VPS, you must personally handle firewalling, updates, hardening, monitoring, backups, Docker/systemd, TLS, and incident response.

Suggested deployment model

Use three environments:

1. Local development machine
2. VPS staging environment
3. Production environment later

Do not expose early development services publicly. Start with SSH-only administration, firewall restrictions, HTTPS only, and private admin access.

Initial server baseline

Minimum for early development:

- 2 vCPU
- 4 GB RAM
- 100 GB NVMe SSD

Recommended for serious development and staging:

- 4 vCPU
- 8 GB RAM
- 200 GB NVMe SSD

Recommended later for production-like testing:

- 8 vCPU
- 16 GB RAM
- 400 GB NVMe SSD

Security checklist

Before deploying Sentinel:

- Use SSH keys, not passwords.
- Disable direct root SSH login.
- Enable firewall rules.
- Keep the system patched.
- Use HTTPS with valid TLS certificates.
- Keep secrets outside the repository.
- Configure backups.
- Configure log rotation.
- Configure monitoring.
- Use least privilege service accounts.
- Do not run development APIs openly on the internet.

Conclusion

For this project, shared hosting should only be used for a public marketing/documentation website. Use Managed VPS for the actual Sentinel application runtime unless you specifically want full responsibility for server administration.
